

Anushree Bajpai ab2167  
Lavani Kumar Velaga pr217

Ans 1:

BFS for cycle with n nodes (tree search)

→ Since there are n nodes  
the node  $v_{n/2}$  will be farthest  
point from  $v_1$ . For each point  
in the cycle there are two  
branches i.e. one on right and left.  
 $\therefore b = 2$ ,  $d = \frac{n}{2}$

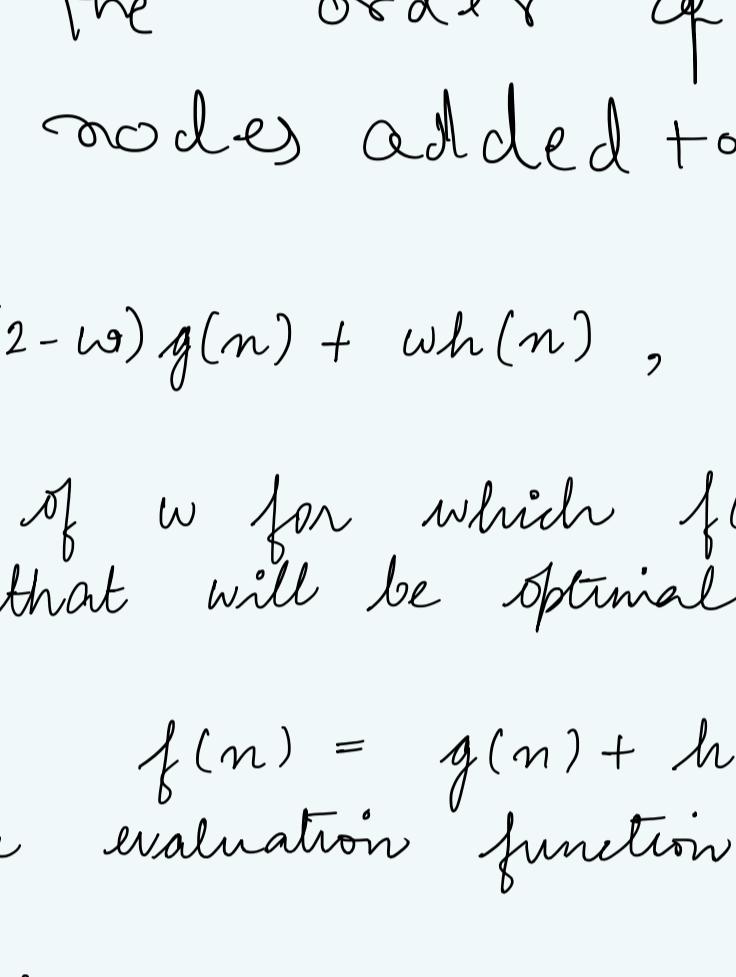

Worst case of number of elements added  
on queue is  $O(b^d) \Rightarrow O(2^{n/2})$

BFS graph search for cycle with n nodes:

→ Since there are n nodes in the  
cycle and the farthest point from  
 $v_1$  is  $v_{n/2}$ . In a graph search each point  
is visited only once as visited list is  
maintained. So, as the search starts from  
 $v_1$  there are two branches i.e.  $v_2$  and  $v_{n-1}$ .  
Where both  $v_2$  and  $v_{n-1}$  traverse through  
all the points without repetition and  
finally reaches  $v_{n/2}$ . So in the process  
we have visited  $n/2$  nodes from  
either end.  
 $\therefore$  total number nodes added to  
queue is maximum of  $n/2 + n/2 = n$   
 $\therefore$  total nodes added is order  $O(n)$

DFS tree search for cycle with n nodes:

Given there are n nodes in cycle  
DFS tree search starts searching  
from  $v_1$  (goes left from  $v_1$ )  
and then the tree expands  
in the same direction until it  
reaches the goal state. So, the maximum  
number of nodes the tree would visit  
would be  $n-1$  (happens when goal is  $v_n$ )

DFS graph search for cycle with n nodes:

Given there are n nodes in cycle  
DFS graph search works similar to tree search starts  
from  $v_1$  (goes left from  $v_1$ )  
and then the tree expands  
in the same direction until it  
reaches the goal state. So, the maximum  
number of nodes the tree would visit  
would be  $n-1$  (happens when goal is  $v_n$ )

 $\therefore O(n)$ DFS graph search for IDS:

In infinite diamond strip given in the  
question, nodes on the left expand  
prior to nodes on the right. As we  
are using DFS graph search, the graph  
continues to expand to the left of  
starting node. Given the goal state  
is on right side of initial state  
the graph will never reach the  
goal state. therefore DFS graph  
expands infinitely to its left.  
 $\therefore$  total nodes added to queue =  $O(\infty)$

DFS tree search for IDS:

In BFS tree search we add  
all the elements into FIFO queue. In  
tree search we visit nodes multiple  
times and they are added to  
queue multiple times.  
 $\therefore$  total nodes visited =  $O(b^d)$   
 $\Rightarrow O(4^d)$   
We know  $b^d = 2^m$   
 $\therefore d = 2^m$   
 $\therefore$  total nodes added to queue =  $O(4^{m/2})$

BFS graph search for IDS:

In BFS graph search we  
do not visit any node multiple  
times i.e. we maintain visited  
list. i.e. the graph is expected  
to traverse on both the direction  
at the same rate. However, the  
graph expands first on left but it  
simultaneously expands even on right.  
If goal is at depth d from initial  
point then we need to traverse  
in the order of  $O(n)$

 $\therefore$  total nodes added to queue =  $O(n)$ Ans 2)  $f(n) = (2-w)g(n) + wh(n)$ ,  $0 \leq w \leq 2$ 

The values of w for which  $f(n)$  represents an  
algorithm that will be optimal is -

- (i) When  $w=1$ ,  $f(n) = g(n) + h(n)$   
which is the evaluation function of A\* algorithm

A\* has the properties -

- the tree search version of A\* is optimal if  $h(n)$  is admissible
- the graph search version of A\* is optimal if  $h(n)$  is consistent.

Hence, when  $w=1$  and  $h$  is admissible, for the case of  
TREE-SEARCH, A\* is guaranteed to be optimal.

- (ii) For  $w=0$ ,  $f(n) = 2g(n)$

This is Uniform cost search as the evaluation function  
only depends on the cost-to-some  $g(n)$ .

Hence, when  $w=0$ , it is Uniform cost search which  
is always guaranteed to find the optimal path.

- (iii) The algorithm is guaranteed to be optimal in the range  $0 \leq w \leq 1$ . Multiplying  $g(n)$  with a value between 1 and 2  
will not impact the order of traversed path. Keeping  $w$  between  
0 and 1 will not lead the heuristic to overestimate the cost.

The search performed by the algorithm following the evaluation  
function  $f(n) = (2-w)g(n) + wh(n)$  is -

- $w=0 \rightarrow$  Uniform cost search  $f(n) = 2g(n)$
- $w=1 \rightarrow A^*$  search  $f(n) = g(n) + h(n)$
- $w=2 \rightarrow$  Greedy Best-First search  $f(n) = h(n)$   
Greedy Best-First search tries to expand the node closest to the  
goal state. It evaluates the nodes just on the basis of  
heuristic function i.e.  $f(n) = h(n)$ .

Ans 3) Heuristic function is an estimated value of the cost-to-go  
function.

- Admissible heuristic: A heuristic is admissible if it never  
overestimates the cost to reach the goal. A heuristic  $h(n)$  is  
admissible if for every node  $n$ ,  $h(n) \leq h^*(n)$  where  
 $h^*(n)$  is the true cost of reaching the goal state from  $n$ .
- Consistent heuristic: A heuristic is consistent if for every node  
 $n$  and every successor  $n'$  of  $n$  generated by any action  $a$ ,  
the estimated cost of reaching the goal from  $n$  is no greater  
than the step cost of getting to  $n'$  plus the estimated cost of  
reaching the goal from  $n'$ :  $h(n) \leq c(n, a, n') + h(n')$

- (i)  $h_{\min}(n) = \min\{h_1(n), h_2(n)\}$

Given that  $h_1(n)$  and  $h_2(n)$  are admissible, we know that  
 $h_1(n) \leq h^*(n)$  and  $h_2(n) \leq h^*(n)$ .  
The minimum out of  $h_1$  and  $h_2$  is also admissible as it is  
either  $h_1$  or  $h_2$  and we already know they are both less than  
or equal to the true cost  $h^*(n)$ .

$\therefore h_{\min}(n)$  is admissible.

Given that  $h_1(n)$  and  $h_2(n)$  are consistent, we know that  
 $h_1(n) \leq c(n, n') + h_1(n')$  and  $h_2(n) \leq c(n, n') + h_2(n')$ .

$$\begin{aligned} h_{\min}(n) &= \min(h_1(n), h_2(n)) \\ &\leq \min(h_1(n') + c(n, n'), h_2(n') + c(n, n')) \\ &\leq \min(h_1(n'), h_2(n')) + c(n, n') \\ &\leq h_{\max}(n') + c(n, n') \end{aligned}$$

$\therefore h_{\min}(n)$  is consistent

- (ii)  $h_{\max} = \max\{h_1(n), h_2(n)\}$

Given that  $h_1(n)$  and  $h_2(n)$  are admissible, we know that  
 $h_1(n) \leq h^*(n)$  and  $h_2(n) \leq h^*(n)$ .  
The maximum out of  $h_1$  and  $h_2$  is also admissible as it is  
either  $h_1$  or  $h_2$  and we already know they are both less than  
or equal to the true cost  $h^*(n)$ .

$\therefore h_{\max}(n)$  is admissible.

Given that  $h_1(n)$  and  $h_2(n)$  are consistent, we know that  
 $h_1(n) \leq c(n, n') + h_1(n')$  and  $h_2(n) \leq c(n, n') + h_2(n')$ .

$$\begin{aligned} h_{\max}(n) &= \max(h_1(n), h_2(n)) \\ &\leq \max(h_1(n') + c(n, n'), h_2(n') + c(n, n')) \\ &\leq \max(h_1(n'), h_2(n')) + c(n, n') \\ &\leq h_{\max}(n') + c(n, n') \end{aligned}$$

$\therefore h_{\max}(n)$  is consistent

- (iii)  $h_{lin}(n) = wh_1(n) + (1-w)h_2(n)$ ,  $0 \leq w \leq 1$

When  $w=0$ ,  $h_{lin} = h_2(n)$   
 $w=1$ ,  $h_{lin} = h_1(n)$

The range of  $h_{lin}(n)$  is  $\min(h_1(n), h_2(n))$  to  
 $\max(h_1(n), h_2(n))$ .

Given that  $h_1(n)$  and  $h_2(n)$  are admissible we have  
already proved that  $\min(h_1(n), h_2(n))$  and  $\max(h_1(n), h_2(n))$   
are admissible.

$\therefore h_{lin}$  is admissible.

We know that  $\max(h_1(n), h_2(n))$  is consistent.  
The maximum value of  $h_{lin}$  is  $\max(h_1(n), h_2(n))$ .

$$h_{lin}(n) \leq h_{\max}(n) \leq h_{\max}(n') + c(n, n') \quad (1)$$

$$h_{lin}(n') \leq h_{\max}(n') \quad (2)$$

From (1) and (2)  $h_{lin}(n) \leq h_{lin}(n') + c(n, n')$

$\therefore h_{lin}(n)$  is consistent.

- (iv)  $h_1$ : number of misplaced tiles  
 $h_2$ : Manhattan distance

Using  $h_1$  heuristic -

When we move any tile to change state,  
the heuristic can change in the following ways :

- If the tile reached its correct position,  $h_1$  will decrease by 1.
- If the tile went from its correct to an incorrect position,  
it will increase by 1.
- If the tile goes to another incorrect position,  $h$  remains unchanged.

For consistency,  $h_1(n) \leq c(n, n') + h_1(n')$

In our case ?  $1 + h_1(n')$

$\therefore$  At most the value of  $h_1(n')$  will be +1 or -1 → the  
value of  $h_1(n)$ . So we can write  
 $h_1(n) \leq 1 + (h_1(n') - 1)$

The left side value will be less than or equal to the  
right side value.  $\therefore h_1$  is consistent.

Using  $h_2$  heuristic -

When we move any tile to change state,  
the heuristic can change in the following ways :

- If the tile moved in a correct direction,  $h_2$  will decrease by 1.
- If the tile moved in an incorrect direction,  $h_2$  will increase by 1.  
So cost will only change (increase/decrease) by 1.

$$h_2(n) \leq c(n, n') + h_2(n') \quad (1)$$

$$h_2(n') \leq 1 + (h_2(n) - 1) \quad (2)$$

From (1) and (2)  $h_2(n) \leq h_2(n') + c(n, n')$

$\therefore h_2(n)$  is consistent.

- (v)  $h_1$ : number of misplaced tiles  
 $h_2$ : Manhattan distance

Using  $h_1$  heuristic -

When we move any tile to change state,  
the heuristic can change in the following ways :

- If the tile reached its correct position,  $h_1$  will decrease by 1.
- If the tile went from its correct to an incorrect position,  
it will increase by 1.
- If the tile goes to another incorrect position,  $h$  remains unchanged.

$$h_1(n) \leq c(n, n') + h_1(n') \quad (1)$$

$$h_1(n') \leq 1 + (h_1(n) - 1) \quad (2)$$

From (1) and (2)  $h_1(n) \leq h_1(n') + c(n, n')$

$\therefore h_1(n)$  is consistent.

- (vi)  $h_1$ : number of misplaced tiles  
 $h_2$ : Manhattan distance

Using  $h_2$  heuristic -

When we move any tile to change state,  
the heuristic can change in the following ways :

- If the tile moved in a correct direction,  $h_2$  will decrease by 1.
- If the tile moved in an incorrect direction,  $h_2$  will increase by 1.  
So cost will only change (increase/decrease) by 1.

$$h_2(n) \leq c(n, n') + h_2(n') \quad (1)$$

$$h_2(n') \leq 1 + (h_2(n) - 1) \quad (2)$$

From (1) and (2)  $h_2(n) \leq h_2(n') + c(n, n')$

$\therefore h_2(n)$  is consistent.

- (vii)  $h_1$ : number of misplaced tiles  
 $h_2$ : Manhattan distance

Using  $h_1$  heuristic -

When we move any tile to change state,  
the heuristic can change in the following ways :

- If the tile reached its correct position,  $h_1$  will decrease by 1.
- If the tile went from its correct to an incorrect position,  
it will increase by 1.
- If the tile goes to another incorrect position,  $h$  remains unchanged.

$$h_1(n) \leq c(n, n') + h_1(n') \quad (1)$$

$$h_1(n') \leq 1 + (h_1(n) - 1) \quad (2)$$

From (1) and (2)  $h_1(n) \leq h_1(n') + c(n, n')$

$\therefore h_1(n)$  is consistent.

- (viii)  $h_1$ : number of misplaced tiles  
 $h_2$ : Manhattan distance

Using  $h_2$  heuristic -
